Abstract Here we review studies that provided important information about conformational properties of DNA using circular dichroic (CD) spectroscopy. The conformational properties include the B-family of structures, A-form, Z-form, guanine quadruplexes, cytosine quadruplexes, triplexes and other less characterized structures.

Circular dichroism is dichroism involving circularly polarized light, i.e., the differential absorption of left- and right-handed light. Left-hand circular and right-hand circular polarized light represent two possible spin angular momentum states for a photon, and so circular dichroism is also referred to as

Circular dichroism - Wikipedia

Circular Dichroism (CD), which is the difference in the absorption of left-handed circularly polarized light and right-handed circularly polarized light that arise due to structural asymmetry, is the technique used for analyzing secondary and tertiary structures and folding properties of proteins in solutions, which could be changed due to its environmental changes such as temperature or pH.

This tutorial review is addressed to readers with a background in basic organic chemistry and spectroscopy, but without a specific knowledge of electronic circular dichroism. It describes the fundamental principles, instrumentation, data analysis, and different approaches for interpretation of ECD. The discussion focuses on the application of ECD, also in combination with other methods, in ...

AbstractThe effect of Zn^{2+} binding on the circular dichroism (CD) spectra of brain-specific S-100a and S-100b calcium-binding proteins has been examined. In the presence of Zn^{2+} , S-100a undergoes a conformational change and the decrease in ellipticity at 222 nm, as a result of Zn^{2+} addition, was nearly $1400 \text{ deg.cm}^2.\text{dmol}^{-1}$, whereas with S-100b there was no significant conformational change.
