Nuclear Reactor Theory. The nuclear reactor theory is based on diffusion theory. The key term of the reactor theory is "criticality" of the reactor. Using the term "criticality" may seem counter-intuitive as a way to describe normalcy. The word often describes situations with potential for disaster.

The theory behind nuclear reactors is built on the basic principles of nuclear physics. Nuclear reactors initiate fission reactions in uranium fuel, which are then controlled using moderators and neutron poisons. These reactions release energy in the form of heat, which is then converted to electricity.

What is the Theory behind Nuclear Reactors? - Bright Hub ...

The steam produced in the reactor flows through moisture separators and dryers inside the reactor vessel to remove moisture prior to exiting the vessel. The dry steam flows to the turbine, where the energy of the steam is used to turn the turbine and generator. The steam is then condensed and the water is pumped back to the reactor.

sustaining, we say the reactor is critical, $k=1$ and the average neutron population (or power) stays constant. - $k>1$: the number of neutrons grows exponentially with time and the reactor is supercritical - $k<1$: the number of neutrons decreases exponentially with time and the reactor is subcritical

Basic Nuclear Physics and Reactor Theory Flashcards | Quizlet

Nuclear reactor physics is the field of physics that studies and deals with the applied study and engineering applications of chain reaction to induce a controlled rate of fission in a nuclear reactor for the production of energy. Most nuclear reactors use a chain reaction to induce a controlled rate of nuclear fission in fissile material, releasing both energy and free neutrons. A reactor consists of an assembly of nuclear fuel, usually surrounded by a neutron moderator such as regular water, h

Nuclear reactor physics - Wikipedia

Chapter 1 Nuclear reactors and nuclear reactions 1.1. Principle of a nuclear reactor In a nuclear reactor certain very heavy nuclei (e.g. ^{235}U) can be split into two fragments by neutrons, whereby a relatively large amount of energy is released and, moreover, a few new neutrons, which in their turn can cause new fissions.
